HETEROPOLYCYCLIC COMPOUNDS AND THEIR USE AS MATABOTROPIC GLUTAMATE RECEPTOR ANTAGONISTS

FIELD OF THE INVENTION

The invention provides compounds active at metabotropic glutamate receptors and that are useful for treating neurological and psychiatric diseases and disorders.

BACKGROUND OF THE INVENTION

5 Recent advances in the elucidation of the neurophysiological roles of metabotropic glutamate receptors have established these receptors as promising drug targets in the therapy of acute and chronic neurological and psychiatric disorders and diseases. However, the major challenge to the realization of this promise has been the development of metabotropic glutamate receptor subtype-selective compounds.

10 Glutamate is the major excitatory neurotransmitter in the mammalian central nervous system (CNS). Glutamate produces its effects on central neurons by binding to and thereby activating cell surface receptors. These receptors have been divided into two major classes, the ionotropic and metabotropic glutamate receptors, based on the structural features of the receptor proteins, the means by which the receptors transduce signals into
15 the cell, and pharmacological profiles.

 The metabotropic glutamate receptors (mGluRs) are G protein-coupled receptors that activate a variety of intracellular second messenger systems following the binding of glutamate. Activation of mGluRs in intact mammalian neurons elicits one or more of the following responses: activation of phospholipase C; increases in phosphoinositide (PI)
20 hydrolysis; intracellular calcium release; activation of phospholipase D; activation or inhibition of adenyl cyclase; increases or decreases in the formation of cyclic adenosine monophosphate (cAMP); activation of guanylyl cyclase; increases in the formation of cyclic guanosine monophosphate (cGMP); activation of phospholipase A₂; increases in

arachidonic acid release; and increases or decreases in the activity of voltage- and ligand-gated ion channels. Schoepp *et al.*, *Trends Pharmacol. Sci.* 14:13 (1993); Schoepp, *Neurochem. Int.* 24:439 (1994); Pin *et al.*, *Neuropharmacology* 34:1 (1995).

Eight distinct mGluR subtypes, termed mGluR1 through mGluR8, have been identified by molecular cloning. See, for example, Nakanishi, *Neuron* 13:1031 (1994); Pin *et al.*, *Neuropharmacology* 34:1 (1995); Knopf *et al.*, *J. Med. Chem.* 38:1417 (1995). Further receptor diversity occurs via expression of alternatively spliced forms of certain mGluR subtypes. Pin *et al.*, *PNAS* 89:10331 (1992); Minakami *et al.*, *BBRC* 199:1136 (1994); Joly *et al.*, *J. Neurosci.* 15:3970 (1995).

Metabotropic glutamate receptor subtypes may be subdivided into three groups, Group I, Group II, and Group III mGluRs, based on amino acid sequence homology, the second messenger systems utilized by the receptors, and by their pharmacological characteristics. Nakanishi, *Neuron* 13:1031 (1994); Pin *et al.*, *Neuropharmacology* 34:1 (1995); Knopf *et al.*, *J. Med. Chem.* 38:1417 (1995).

Group I mGluRs comprise mGluR1, mGluR5, and their alternatively spliced variants. The binding of agonists to these receptors results in the activation of phospholipase C and the subsequent mobilization of intracellular calcium. Electrophysiological measurements have been used to demonstrate these effects, for example, in *Xenopus* oocytes that express recombinant mGluR1 receptors. See, for example, Masu *et al.*, *Nature* 349:760 (1991); Pin *et al.*, *PNAS* 89:10331 (1992). Similar results have been achieved with oocytes expressing recombinant mGluR5 receptors. Abe *et al.*, *J. Biol. Chem.* 267:13361 (1992); Minakami *et al.*, *BBRC* 199:1136 (1994); Joly *et al.*, *J. Neurosci.* 15:3970 (1995). Alternatively, agonist activation of recombinant mGluR1 receptors expressed in Chinese hamster ovary (CHO) cells stimulates PI hydrolysis, cAMP formation, and arachidonic acid release as measured by standard biochemical assays. Aramori *et al.*, *Neuron* 8:757 (1992).

By comparison, the activation of mGluR5 receptors, expressed in CHO cells, stimulates PI hydrolysis and subsequent intracellular calcium transients, but no stimulation of cAMP formation or arachidonic acid release is observed. Abe *et al.*, *J. Biol. Chem.* 267:13361 (1992). However, activation of mGluR5 receptors expressed in LLC-PK1 cells results in PI hydrolysis and increased cAMP formation. Joly *et al.*, *J. Neurosci.* 15:3970 (1995). The agonist potency profile for Group I mGluRs is quisqualate > glutamate = ibotenate > (2*S*,1'*S*,2'*S*)-2-carboxycyclopropylglycine (L-CCG-I) > (1*S*,3*R*)-1-

aminocyclopentane-1,3-dicarboxylic acid (ACPD). Quisqualate is relatively selective for Group I receptors, as compared to Group II and Group III mGluRs, but it also is a potent activator of ionotropic AMPA receptors. Pin *et al.*, *Neuropharmacology* 34:1, Knopfel *et al.*, *J. Med. Chem.* 38:1417 (1995).

5 The lack of subtype-specific mGluR agonists and antagonists has impeded elucidation of the physiological roles of particular mGluRs, and the mGluR-associated pathophysiological processes that affect the CNS have yet to be defined. However, work with the available non-specific agonists and antagonists has yielded some general insights about the Group I mGluRs as compared to the Group II and Group III mGluRs.

10 Attempts at elucidating the physiological roles of Group I mGluRs suggest that activation of these receptors elicits neuronal excitation. Various studies have demonstrated that ACPD can produce postsynaptic excitation upon application to neurons in the hippocampus, cerebral cortex, cerebellum, and thalamus, as well as other brain regions. Evidence indicates that this excitation is due to direct activation of postsynaptic mGluRs, but it also has been suggested that activation of presynaptic mGluRs occurs, resulting in increased neurotransmitter release. Baskys, *Trends Pharmacol. Sci.* 15:92 (1992); Schoepp, *Neurochem. Int.* 24:439 (1994); Pin *et al.*, *Neuropharmacology* 34:1(1995).

20 Pharmacological experiments implicate Group I mGluRs as the mediators of this excitatory mechanism. The effects of ACPD can be reproduced by low concentrations of quisqualate in the presence of iGluR antagonists. Hu *et al.*, *Brain Res.* 568:339 (1991); Greene *et al.*, *Eur. J. Pharmacol.* 226:279 (1992). Two phenylglycine compounds known to activate mGluR1, namely (*S*)-3-hydroxyphenylglycine ((*S*)-3HPG) and (*S*)-3,5-dihydroxyphenylglycine ((*S*)-DHPG), also produce excitation. Watkins *et al.*, *Trends Pharmacol. Sci.* 15:33 (1994). In addition, the excitation can be blocked by (*S*)-4-carboxyphenylglycine ((*S*)-4CPG), (*S*)-4-carboxy-3-hydroxyphenylglycine ((*S*)-4C3HPG), and (+)-alpha-methyl-4-carboxyphenylglycine ((+)-MCPG), compounds known to be mGluR1 antagonists. Eaton *et al.*, *Eur. J. Pharmacol.* 244:195 (1993); Watkins *et al.*, *Trends Pharmacol. Sci.* 15:333 (1994).

25 Metabotropic glutamate receptors have been implicated in a number of normal processes in the mammalian CNS. Activation of mGluRs has been shown to be required for induction of hippocampal long-term potentiation and cerebellar long-term depression. Bashir *et al.*, *Nature* 363:347 (1993); Bortolotto *et al.*, *Nature* 368:740 (1994); Aiba *et al.*, *Cell* 79:365 (1994); Aiba *et al.*, *Cell* 79:377 (1994). A role for mGluR activation in

nociception and analgesia also has been demonstrated. Meller *et al.*, *Neuroreport* 4: 879 (1993). In addition, mGluR activation has been suggested to play a modulatory role in a variety of other normal processes including synaptic transmission, neuronal development, apoptotic neuronal death, synaptic plasticity, spatial learning, olfactory memory, central control of cardiac activity, waking, motor control, and control of the vestibulo-ocular reflex. Generally, see Nakanishi, *Neuron* 13: 1031 (1994); Pin *et al.*, *Neuropharmacology* 34:1; Knopfel *et al.*, *J. Med. Chem.* 38:1417 (1995).

Metabotropic glutamate receptors also have been suggested to play roles in a variety of pathophysiological processes and disease states affecting the CNS. These include stroke, head trauma, anoxic and ischemic injuries, hypoglycemia, epilepsy, and neurodegenerative diseases such as Alzheimer's disease. Schoepp *et al.*, *Trends Pharmacol. Sci.* 14:13 (1993); Cunningham *et al.*, *Life Sci.* 54:135 (1994); Hollman *et al.*, *Ann. Rev. Neurosci.* 17:31 (1994); Pin *et al.*, *Neuropharmacology* 34:1 (1995); Knopfel *et al.*, *J. Med. Chem.* 38:1417 (1995). Much of the pathology in these conditions is thought to be due to excessive glutamate-induced excitation of CNS neurons. Because Group I mGluRs appear to increase glutamate-mediated neuronal excitation via postsynaptic mechanisms and enhanced presynaptic glutamate release, their activation probably contributes to the pathology. Accordingly, selective antagonists of Group I mGluR receptors could be therapeutically beneficial, specifically as neuroprotective agents, analgesics, or anticonvulsants.

Preliminary studies assessing therapeutic potentials with the available mGluR agonists and antagonists have yielded seemingly contradictory results. For example, it has been reported that application of ACPD onto hippocampal neurons leads to seizures and neuronal damage (Sacaan *et al.*, *Neurosci. Lett.* 139:77 (1992); Lipparti *et al.*, *Life Sci.* 52:85 (1993). Other studies indicate, however, that ACPD inhibits epileptiform activity, and also can exhibit neuroprotective properties. Taschenberger *et al.*, *Neuroreport* 3:629 (1992); Sheardown, *Neuroreport* 3:916 (1992); Koh *et al.*, *Proc. Natl. Acad. Sci. USA* 88:9431 (1991); Chiamulera *et al.*, *Eur. J. Pharmacol.* 216:335 (1992); Siliprandi *et al.*, *Eur. J. Pharmacol.* 219:173 (1992); Pizzi *et al.*, *J. Neurochem.* 61:683 (1993).

It is likely that these conflicting results are due to the lack of selectivity of ACPD, which causes activation of several different mGluR subtypes. In the studies finding neuronal damage it appears that Group I mGluRs were activated, thereby enhancing undesirable excitatory neurotransmission. In the studies showing neuroprotective effects it

appears that activation of Group II and/or Group III mGluRs occurred, inhibiting presynaptic glutamate release, and diminishing excitatory neurotransmission.

This interpretation is consistent with the observation that (S)-4C3HPG, a Group I mGluR antagonist and Group II mGluR agonist, protects against audiogenic seizures in DBA/2 mice, while the Group II mGluR selective agonists DCG-IV and L-CCG-I protect neurons from NMDA- and KA-induced toxicity. Thomsen *et al.*, *J. Neurochem.* 62:2492 (1994); Bruno *et al.*, *Eur. J. Pharmacol.* 256:109 (1994); Pizzi *et al.*, *J. Neurochem.* 61:683 (1993).

Based on the foregoing, it is clear that currently available mGluR agonists and antagonists have limited value, due to their lack of potency and selectivity. In addition, most currently available compounds are amino acids or amino acid derivatives that have limited bioavailabilities, thereby hampering *in vivo* studies to assess mGluR physiology, pharmacology and their therapeutic potential. Compounds that selectively inhibit activation of metabotropic glutamate receptor Group I subtypes should be useful for treatment of neurological disorders and diseases such as senile dementia, Parkinson's disease, Alzheimer's disease, Huntington's Chorea, pain, migraine headaches, epilepsy, head trauma, anoxic and ischemic injuries, psychiatric disorders such as schizophrenia, depression, and anxiety, ophthalmological disorders such as various retinopathies, for example, diabetic retinopathies, glaucoma, and neurological disorders of a auditory nature such as tinnitus, and neuropathic pain disorders, including neuropathic diseases states such as diabetic neuropathies, chemotherapy induced neuropathies, post-herpetic neuralgia, and trigeminal neuralgia.

Accordingly, a need exists for potent mGluR agonists and antagonists that display a high selectivity for a mGluR subtype, particularly a Group I receptor subtype.

Chem.* 61, 4623-4633 (1996). 3,5-Disubstituted-1,3-Oxazoles were prepared by reacting a haloketone with carboxamide in refluxing toluene for 3 days. The resulting mixture was allowed to cool to room temperature, the solvent was removed and the residue was purified.

DETAILED DESCRIPTION OF THE INVENTION

25 The present invention provides compounds that are potent and selective antagonists of mGluR5. The compounds contemplated by the invention can be represented by the general formula I:

where Ar^1 is an optionally substituted heterocyclic moiety and Ar^2 is an optionally substituted carbocyclic moiety. The G moiety is a group that not only covalently binds to

Structure of the Ar¹ and Ar² moieties

The Ar¹ moiety is generally defined as a heterocyclic moiety, and the Ar² moiety is generally defined as a carbocyclic moiety. Ar¹ and Ar² can be monocyclic or fused bicyclic groups. Ar² is preferably defined as an aryl or alkaryl moiety. Ar¹ is preferably defined as a heterocyclic, heteroaryl or heteroarylalkyl moiety. The ring systems encompassed by Ar¹ can contain up to four heteroatoms, independently selected from the group consisting of N, S, and O. Preparation of mGluR Group I antagonists

Many starting materials for preparing the compounds of the present invention are available from commercial sources, such as Aldrich Chemical Company (Milwaukee, WI). Moreover, compounds of the invention are readily prepared, from available precursors, using straightforward transformations which are well known in the art. The skilled artisan will recognize that mGluR Group I antagonists, according to the invention, can be prepared via methodology that is well known, using widely recognized techniques of organic chemistry. Suitable reactions are described in standard textbooks of organic chemistry. For example, see March, ADVANCED ORGANIC CHEMISTRY, 2d ed., McGraw Hill (1977).

More specifically, compounds of the invention generally can be prepared by formation of the G moiety between two precursor compounds containing suitable Ar¹ and Ar² moieties. When the linker contains a 1,2,4-oxadiazole, the heterocycle may be formed using well known techniques, such as reaction between an amidoxime and an acid chloride, or by the reaction of an amidoxime and an acylimidazole. An illustration of such a transformation is provided in Examples 3 through 6, below.

Amidoximes can be prepared using well known techniques by the reaction of an Ar¹ substituted nitrile with hydroxylamine. An illustration of such a transformation is provided below in Example 1.

In most cases, the precursor Ar² acid chlorides are readily available, or may be prepared using straightforward techniques of organic chemistry. For example, carboxylic acids may be converted into the corresponding acid chlorides by reaction with, for example, thionyl chloride or oxalyl chloride.

In the case where the linker contains a 1,3-oxazole, compounds were prepared using a procedure similar to that given by Kelly *et al.*, *J. Org. Chem.* 61, 4623-4633 (1996). Thus, 3,5-Disubstituted-1,3-Oxazoles were prepared by mixing a haloketone with

carboxamide in refluxing toluene for 3 days. The resulting mixture was allowed to cool to room temperature, the solvent was removed and the residue was purified.

Testing of compounds for mGluR Group I antagonist activity

The pharmacological properties of the compounds of the invention can be analyzed using standard assays for functional activity. Examples of glutamate receptor assays are well known in the art, for example, see Aramori *et al.*, *Neuron* 8:757 (1992); Tanabe *et al.*, *Neuron* 8:169 (1992); Miller *et al.*, *J. Neuroscience* 15: 6103 (1995); Balazs, *et al.*, *J. Neurochemistry* 69:151 (1997). The methodology described in those publications is incorporated herein by reference.

Conveniently, the compounds of the invention can be studied by means of an assay that measures the mobilization intracellular calcium, $[Ca^{2+}]_i$ in cells expressing mGluR5 that can bind the compounds. A well-known cell line which is suitable for this purpose is described in Miller *et al.*, *J. Neuroscience* 15: 6103 (1995), the contents of which are hereby incorporated by reference. It has been shown that exposure of rat astrocytes to the growth factors basic fibroblast growth factor, EGF, or transforming growth factor- α markedly increased the protein expression and functional activity of endogenous mGluR5 (Miller *et al.*, *J. Neuroscience*, 15(9): 6103-6109, 1995).

In brief, primary astrocyte cultures were prepared from 3-5 day old Sprague-Dawley rat pups using a modification of Miller *et al.* and were plated on poly-L lysine coated flasks in Dulbecco's modified Eagle's medium (DMEM) containing fetal calf serum (FCS). For cuvette analysis, cultures were up-regulated with growth factors in flasks for 3-5 days, then harvested and prepared for measurement of $[Ca^{2+}]_i$ mobilization as previously described (Nemeth *et al.*, 1998).

For fluorescent imaging plate reader (FLIPR) analysis, cells were seeded on poly-D lysine coated clear bottom 96-well plates with black sides and analysis of $[Ca^{2+}]_i$ mobilization was performed 3 days following the growth factor up-regulation.

FLIPR experiments were carried out using a laser setting of 0.800 W and a 0.4 second CCD camera shutter speed. Each FLIPR experiment was initiated with 180 μ L of buffer present in each well of the cell plate. After each addition of compound, the fluorescence signal was sampled 50 times at 1 second intervals followed by 3 samples at 5 second intervals. Responses were measured as the peak height of the response within the sample period.

EC₅₀ and IC₅₀ determinations were made from data obtained from 8 point concentration response curves (CRC) performed in duplicate. Agonist CRC were generated by scaling all responses to the maximal response observed for the plate. Antagonist block of the agonist challenge was normalized to the average response of the agonist challenge in 14 control wells on the same plate. A detailed protocol for testing the compounds of the invention is provided below at Example 4.

The exact dosage will depend upon the route of administration, the form in which the compound is administered, the subject to be treated, the body weight of the subject to be treated, and the preference and experience of the attending physician.

The preparations formulated for oral administration may be in the form of tablets, dragees, capsules, or solutions.

Pharmaceutical preparations for oral use can be obtained by combining the active compounds with solid excipients, optionally grinding a resulting mixture, and processing the mixture of granules, after adding suitable auxiliaries, if desired, to obtain tablets or dragee cores. Suitable excipients are, in particular, fillers such as sugars, including lactose, sucrose, mannitol, or sorbitol; cellulose preparations, for example, maize starch, wheat starch, rice starch, potato starch, gelatin, gum tragacanth, methyl cellulose, hydroxypropylmethyl-cellulose, sodium carboxymethyl-cellulose (CMC), and/or polyvinylpyrrolidone (PVP: povidone). Example 1: Synthesis of amidoxime intermediates

Pyrid-2-ylamidoxime

Using the procedure of Shine et al., *J. Heterocyclic Chem.* (1989) 26:125-128, hydroxylamine hydrochloride (7.65 g, 110 mmol) in ethanol (100 mL) was treated with a solution of sodium hydroxide (11 mL of 10 N, 110 mmol). A precipitate quickly formed and the reaction mixture was stirred at ambient temperature for 30 min. The inorganic precipitate was filtered and rinsed with ethanol (100 mL). The filtrate and ethanol washings were combined and treated with 2-cyanopyridine (10.4 g, 100 mmol). The reaction mixture was heated at reflux for 20 hours. The volatiles were then removed *in vacuo* to afford 13.3 g (97%) of pyrid-2-ylamidoxime.

Example 3: Synthesis of 3,5-disubstituted-1,2,4-oxadiazoles from acid chlorides

In general, modifications were made from the procedures given Shine et al., *J. Heterocyclic Chem.* (1989) 26:125-128. 3,5-Disubstituted-1,2,4-oxadiazoles were typically made by adding an acylchloride to a solution of an amidoxime in pyridine after which the reaction mixture was either heated to reflux or placed in a sealed tube and heated. Typically, the oxadiazoles were isolated by precipitating with cold water and filtering or by extraction with an organic solvent. If necessary, the oxadiazoles were purified by chromatography or recrystallization.

5 A mixture of 3-chlorobenzoic acid (0.5 g, 3.19 mmol), 1,3-dicyclohexylcarbodiimide (0.72 g, 3.51 mmol), 4-dimethylaminopyridine (0.04 g, 0.32 mmol) in ethanol was stirred at ambient temperature for 1.5 hour. The white solid was filtered off and the filtrate diluted with dichloromethane (100 mL). The organic solution was washed with 1 *N* sodium hydrogen sulfate (100 mL), saturated sodium bicarbonate
10 (100 mL), water (100 mL) and brine (100 mL). The organic phase was dried over anhydrous magnesium sulfate and filtered. The filtrate was concentrated *in vacuo*. The crude residue was dissolved in ethanol (15 mL) and treated with hydrazine monohydrate (0.46 mL, 9.58 mmol). The resulting clear solution was stirred overnight at ambient temperature. The reaction mixture was then concentrated to dryness *in vacuo*. Silica gel
15 chromatography of the residue, using 3% methanol in dichloromethane, afforded 0.29 g (53%) of 3-chlorobenzhydrazide as a white solid.

3-(2-Pyridyl)-5-(3-chlorophenyl)-1,2,4-triazole (B55)

20 Using the procedures of Browne et al., *Aust. J. Chem.*, (1975) 28:2543-2546, a solution of 2-cyanopyridine (0.1 mL, 1.00 mmol) in methanol (5 mL) was treated with sodium metal (6.9 mg, 0.30 mmol) and stirred for at ambient temperature for 1 hour. After this time, a solution of 3-chlorobenzhydrazide (0.17 g, 1.0 mmol) in methanol (5 mL) was added and the resulting solution heated at reflux for 3 hours. The reaction mixture
25 was concentrated *in vacuo*, and the resulting yellow solid (100 mg) dissolved in toluene (2 mL). The mixture was heated at 175 °C for 3 hours and then stirred overnight at ambient temperature. Evaporation of the solvent *in vacuo* and silica gel chromatography using 1% methanol in dichloromethane afforded 29 mg (11%) of 3-(2-pyridyl)-5-(3-chlorophenyl)-1,2,4-triazole as an off-white solid.

3-(2-Pyridyl)-5-(3-iodophenyl)-1,2,4-triazole (B56)

In a similar fashion, 2-cyanopyridine (0.15 mL, 1.53 mmol), sodium metal (10.5 mg, 0.46 mmol) and 3-iodobenzhydrazide (0.40 g, 1.53 mmol) afforded, after work up and chromatography, 210 mg (40%) of 3-(2-pyridyl)-5-(3-iodophenyl)-1,2,4-triazole as a white solid.

Example 10: Assays of Group I receptor antagonist activity**Astrocyte Screening Assay**

Primary astrocyte cultures were prepared from 3-5 day old Sprague-Dawley rat pups using a modification of Miller (Miller *et al*, *J. Neuroscience*, 15(9): 6103-6109, 1995). In brief, primary cultures were plated on poly-L lysine coated flasks in Dulbecco's modified Eagle's medium (DMEM) containing fetal calf serum (FCS). After 6 days, cell cultures were shaken over night at 280 rpm, then transferred to astrocyte-defined media (ADM) containing growth factors that up-regulate the expression of mGluR5 (Miller et al., 1995). For cuvette analysis, cultures were up-regulated with growth factors in flasks for 3-5 days, then harvested and prepared for measurement of $[Ca^{2+}]_i$ mobilization as previously described (Nemeth et al., 1998).

For FLIPR analysis, cells were seeded on poly-D lysine coated clear bottom 96-well plates with black sides and analysis of $[Ca^{2+}]_i$ mobilization was performed 3 days following the growth factor up-regulation. Cell cultures in the 96-well plates were loaded with a 4 μ M solution of acetoxymethyl ester form of the fluorescent calcium indicator fluo-3 (Molecular Probes, Eugene, Oregon) in 0.01% pluronic. All assays were performed in a buffer containing 127 mM NaCl, 5 mM KCl, 2 mM $MgCl_2$, 0.7 mM NaH_2PO_4 , 2 mM $CaCl_2$, 0.422 mg/ml $NaHCO_3$, 2.4 mg/ml HEPES, 1.8 mg/ml glucose and 1 mg/ml BSA Fraction IV (pH 7.4).

FLIPR experiments were done using a laser setting of 0.800 W and a 0.4 second CCD camera shutter speed. Each FLIPR experiment was initiated with 180 μ L of buffer present in each well of the cell plate. A 20 μ L addition from the antagonist plate was

followed by a 50 μ L addition from the agonist plate. After each addition the fluorescence signal was sampled 50 times at 1 second intervals followed by 3 samples at 5 second intervals. Responses were measured as the peak height of the response within the sample period.

5 EC₅₀/IC₅₀ determinations were made from data obtained from 8 point concentration response curves (CRC) performed in duplicate. Agonist CRC were generated by scaling all responses to the maximal response observed for the plate. Antagonist block of the agonist challenge was normalized to the average response of the agonist challenge in 14 control wells on the same plate.

10 **CaR/mGluR5d Screening Assay**

HEK 293 cells expressing the chimeric CaR/mGluR5d receptor (clonal cell line hCaR/hmGluR5d_hek6) are plated 24 hours prior to assay at a density of 100,000 cells per well in Collagen I-coated 96-well black, clear bottom plates (Becton Dickinson) in DMEM
15 supplemented with 10% FBS (Hyclone).

On the day of the assay, tissue culture medium is aspirated from the wells of a plate and 80 μ L of Assay Buffer (Assay Buffer is: 20 mM HEPES, 146 mM NaCl, 5 mM KCl, 1 mM MgCl₂, 1 mM CaCl₂, 1 mg/ml BSA, 1 mg/ml glucose, pH 7.4) supplemented with 6 μ M of the Ca²⁺-sensitive dye, Fluo-3 AM (Molecular Probes) and 0.025% Pluronic
20 (Molecular Probes) is added to each well. The plate is then incubated in the dark for 1 hour at room temperature to efficiently load the cells with Fluo-3. At the end of the incubation, extracellular Fluo-3 is removed by washing the plate with Assay buffer. Assay Buffer is added back to each well (final volume = 160 μ L) prior to beginning the assay.

The plate is loaded into a FLIPR robotic device (Molecular Devices) with the laser
25 setting at 0.8 Watts. At a time of 10 seconds after initiation of the assay, 40 μ L of Assay Buffer containing 62.5 μ M test substance and 2% DMSO is added to the 160 μ L of Assay Buffer in each well of the plate to yield a final concentration of 12 μ M test substance and 0.4% DMSO. At a time of 75 seconds after initiation of the assay, 50 μ L of Assay Buffer containing 6 mM CaCl₂ is added to the 200 μ L present in each well to yield a final Ca²⁺
30 concentration of 2.0 mM, and a final concentration of test substance of 10 nM. Relative fluorescence intensity (excitation λ = 488 nm / emission λ = 510 nm) is monitored at

relevant time intervals throughout the assay period to measure receptor activation and/or inhibition.

By way of illustration, a 1,2,4-oxadiazole disclosed above, designated "B21" (see Example 3), had an IC_{50} value of 43 nM in relation to CaR/mGluR_{5a} and an IC_{50} value of 121 nM on the native receptor, mGluR_{5a}. A corresponding 1,3 oxazole, designated "B52" (see Example 7), was found to be equipotent on the CaR/mGluR_{5a} chimera, with an IC_{50} value of 45 nM, but displayed increased potency on the native mGluR_{5a} receptor, with an IC_{50} value of 74 nM.

The invention thus has been disclosed broadly and illustrated in reference to representative embodiments described above. Those skilled in the art will recognize that various modifications can be made to the present invention without departing from the spirit and scope thereof.

Continuation of Box I.2

Claims Nos.: 1, 2, 7, 9, 10, 15, 17, 18, 23, 25-28 (all partly)

Present claims 1, 2, 7, 9, 10, 15, 17, 18, 23 and 25-28 relate to an extremely large number of possible compounds and their use. The initial phase of the search revealed a very large number of documents relevant to the issue of novelty of said claims. So many documents were retrieved that it is impossible to determine which parts of those claims may be said to define subject-matter for which protection might legitimately be sought (Article 6 PCT). It appears furthermore that support within the meaning of Article 6 PCT and disclosure within the meaning of Article 5 PCT is to be found for only a very small proportion of the claimed compounds. In the present case, the above mentioned claims so lack novelty and support, and the application so lacks disclosure, that it appears impossible to execute a meaningful search and to issue a complete search report over the whole breadth of the said claims. The search and the report for those claims can only be considered complete for the compounds as defined in claims 3-6 and 8, and their use.

The applicant's attention is drawn to the fact that claims, or parts of claims, relating to inventions in respect of which no international search report has been established need not be the subject of an international preliminary examination (Rule 66.1(e) PCT). The applicant is advised that the EPO policy when acting as an International Preliminary Examining Authority is normally not to carry out a preliminary examination on matter which has not been searched. This is the case irrespective of whether or not the claims are amended following receipt of the search report or during any Chapter II procedure.
